

1. Hint: Use idea from exchange argument for MST correctness.

Proof:

For a contradiction, suppose  $T$  is a MST that does not contain  $e$ .

Then  $T$  contains some path between the endpoints of  $e$ .

Pick some edge  $e'$  on this path.

Then  $T' = T \cup \{e\} - \{e'\}$  is a spanning tree (as in the proof).

But  $c(T') = c(T) + c(e) - c(e') < c(T)$  because  $c(e') > c(e)$   
(by assumption,  $c(e)$  is minimum and unique).

This contradicts the fact that  $T$  is a MST.

2. Hint: Think about when it is "safe" to remove edges without disconnecting a graph.

Counter-example:

$G = a \text{ --1-- } b \text{ --2-- } c \text{ --4-- } d$   
 $\quad \quad \quad \backslash \quad \quad \quad /$   
 $\quad \quad \quad \quad \quad \quad 3 \quad \quad \quad$

Additional condition:

If  $e$  belongs to some cycle  $C$  in  $G$ , then  $e$  belongs to no MST.

Proof:

Hint: You need an exchange argument different from the one in class (adding an edge to a tree and removing another edge from the cycle that results). Instead, you want to remove an edge from a tree then add another edge to connect the two components that result.

For a contradiction, suppose  $e$  belongs to a MST  $T$ .

Consider  $T - \{e\}$ . This is made up of two connected components. Because  $e$  belongs to some cycle  $C$ , there is a way to get from one endpoint of  $e$  to the other along this cycle. So there is at least one edge  $e'$  of  $C$  that connects both components.

Then  $T' = T \cup \{e'\} - \{e\}$  is a spanning tree, and  
 $c(T') = c(T) + c(e') - c(e) < c(T)$  because  $c(e') < c(e)$   
(by assumption,  $c(e)$  is maximum and unique).

This contradicts the fact that  $T$  is a MST.

3. Hint 1: Try to use same proof structure as before.  
 Hint 2 (Reminder): Beware! You need to define "promising" and "extends" carefully to work with the algorithm!  
 Hint 3: Exchange lemma will be different from the one in class, to match structure of algorithm. This will require the idea from above (working with cycles).

Def: MST  $T^*$  "extends"  $T_i$  iff  $T^* \setminus T_i \subseteq \{e_{i+1}, \dots, e_m\}$ .  
 Def:  $T_i$  "promising" iff some  $T^*$  extends  $T_i$ .  
 Proof:  $T_i$  promising for all  $i$ .  
 BC:  $T^* \setminus T_0 \subseteq \{e_1, \dots, e_m\}$  for all MSTs  $T^*$ .  
 I.H.: For some  $i \geq 0$ , suppose  $T^*$  extends  $T_i$ .  
 I.S.: Either  $T_{i+1} = T_i$  or  $T_{i+1} = T_i - \{e_{i+1}\}$ .  
 - Case 1:  $T_{i+1} = T_i$  when  $T_i - \{e_{i+1}\}$  is disconnected, so  $e_{i+1}$  must belong to  $T^*$ , i.e.,  $T^*$  extends  $T_{i+1}$ .  
 - Case 2:  $T_{i+1} = T_i - \{e_{i+1}\}$ . Either  $e_{i+1} \in T^*$  or  $e_{i+1} \notin T^*$ .  
   . Subcase 2.1:  $e_{i+1} \notin T^*$  implies  $T^*$  extends  $T_{i+1}$ .  
   . Subcase 2.2:  $e_{i+1} \in T^*$ .  
     Consider  $T^* - \{e_{i+1}\}$ : two components  $A, B$  (subsets of vertices).  
     But endpoints of  $e_{i+1}$  still connected in  $T_{i+1}$ : some edge  $e_j$  in  $T_{i+1}$  crosses between  $A, B$ .  
     Because  $T_i \setminus T^* \subseteq \{e_{i+1}, \dots, e_m\}$ , must have  $j > i+1$  so  $w(e_j) \leq w(e_{i+1})$ . Let  $T^{**} = T^* - \{e_{i+1}\} \cup \{e_j\}$ .  
     Then  $w(T^{**}) \leq w(T^*)$  so  $T^{**}$  is a MST and extends  $T_{i+1}$ .  
 Conclusion: every  $T_i$  promising  $\Rightarrow T_m$  promising  $\Rightarrow T_m = T^*$  for some MST  $\Rightarrow T_m$  is a MST.
